

# Progressive Supranuclear Palsy (PSP)

## **PSP is a degenerative disorder of the brain with no cure at present.**

The difficulty in diagnosing PSP has led to the creation of red flags to act as warning signs that may raise clinical suspicion of PSP

- Rare neurodegenerative disease, the most common parkinsonian disorder after Parkinson's disease (PD).
- Originally described in 1964 as Steele-Richardson-Olzewski Syndrome.
- Often mistakenly diagnosed as PD due to the similarity of early symptoms.
- Symptoms include early postural instability, supranuclear gaze palsy (paralysis of voluntary vertical gaze with preserved reflexive eye movements), and levodopa-non-responsive parkinsonism.
- Onset of symptoms is typically symmetric.
- Pathologically classified as a tauopathy (abnormal accumulation of the tau protein in the brain).
- Five to seven cases per 100,000 people.
- Slightly more common in men.
- Average age of onset is 63 years, but can occur as early as age 40.
- Life expectancy is five to seven years following symptom onset.
- No known way to reverse or stop the progression, though many symptoms can be reduced with medication or other therapy.

## **Signs and Symptoms**

- Early onset gait and balance problems
- Clumsy gait or slow, shuffling gait
- Lack of coordination
- Slowed or absent balance reactions/postural instability
- Frequent falls (most often backward)
- Slowed movements
- Rigidity (generally axial)
- Vertical gaze palsy
- Generally downward gaze loss is first
- Abnormal eyelid control
- Decreased blinking with “staring” look
- Blepharospams (involuntary eyelid spasms)
- Double vision
- Dystonia – commonly at neck and hands into flexion, but can also be into extension at neck
- Speech and swallowing changes
- Subcortical dementia (personality changes, slowness of thought)
- “Rocket sign,” when patient jumps up quickly from seated position, often falling back in chair
- Depression and/or anxiety
